# Engineering Cryptographic Software Multiprecision arithmetic

Radboud University, Nijmegen, The Netherlands

Winter 2025/26

- Asymmetric cryptography heavily relies on arithmetic on "big integers"
- ► Example 1: RSA-2048 needs (modular) multiplication and squaring of 2048-bit numbers

- Asymmetric cryptography heavily relies on arithmetic on "big integers"
- ► Example 1: RSA-2048 needs (modular) multiplication and squaring of 2048-bit numbers
- Example 2:
  - Elliptic curves defined over finite fields
  - ► Typically use EC over large-characteristic prime fields
  - ▶ Typical field sizes: (160 bits, 192 bits), 256 bits, 448 bits . . .

- Asymmetric cryptography heavily relies on arithmetic on "big integers"
- ► Example 1: RSA-2048 needs (modular) multiplication and squaring of 2048-bit numbers
- Example 2:
  - ► Elliptic curves defined over finite fields
  - ► Typically use EC over large-characteristic prime fields
  - ▶ Typical field sizes: (160 bits, 192 bits), 256 bits, 448 bits . . .
- Example 3: Poly1305 needs arithmetic on 130-bit integers

- Asymmetric cryptography heavily relies on arithmetic on "big integers"
- ► Example 1: RSA-2048 needs (modular) multiplication and squaring of 2048-bit numbers
- Example 2:
  - Elliptic curves defined over finite fields
  - ► Typically use EC over large-characteristic prime fields
  - ▶ Typical field sizes: (160 bits, 192 bits), 256 bits, 448 bits . . .
- Example 3: Poly1305 needs arithmetic on 130-bit integers
- An integer is "big" if it's not natively supported by the machine architecture
- Example: AMD64 supports up to 64-bit integers, multiplication produces 128-bit result, but not bigger than that.
- ▶ We call arithmetic on such "big integers" multiprecision arithmetic

- Asymmetric cryptography heavily relies on arithmetic on "big integers"
- ► Example 1: RSA-2048 needs (modular) multiplication and squaring of 2048-bit numbers
- Example 2:
  - Elliptic curves defined over finite fields
  - ► Typically use EC over large-characteristic prime fields
  - ▶ Typical field sizes: (160 bits, 192 bits), 256 bits, 448 bits . . .
- Example 3: Poly1305 needs arithmetic on 130-bit integers
- An integer is "big" if it's not natively supported by the machine architecture
- Example: AMD64 supports up to 64-bit integers, multiplication produces 128-bit result, but not bigger than that.
- ▶ We call arithmetic on such "big integers" multiprecision arithmetic
- ► For now mainly interested in 160-bit and 256-bit arithmetic
- Example architecture for today (most of the time): AVR ATmega

Available numbers (digits): (0), 1, 2, 3, 4, 5, 6, 7, 8, 9

**Available numbers (digits):** (0), 1, 2, 3, 4, 5, 6, 7, 8, 9

#### Addition

- 3 + 5 = ?
- 2 + 7 = ?
- 4 + 3 = ?

Available numbers (digits): (0), 1, 2, 3, 4, 5, 6, 7, 8, 9

#### Addition

- 3 + 5 = ?
- 2 + 7 = ?
- 4 + 3 = ?

#### Subtraction

- 7 5 = ?
- 5 1 = ?
- 9 3 = ?

**Available numbers (digits):** (0), 1, 2, 3, 4, 5, 6, 7, 8, 9

#### Addition

# 3+5=?

$$2 + 7 = ?$$

$$4 + 3 = ?$$

#### Subtraction

$$7 - 5 = ?$$

$$5 - 1 = ?$$

$$9 - 3 = ?$$

- ► All results are in the set of available numbers
- ► No confusion for first-year school kids

Available numbers:  $0, 1, \dots, 255$ 

Available numbers:  $0, 1, \ldots, 255$ 

#### Addition

```
uint8_t a = 42;
uint8_t b = 89;
uint8_t r = a + b;
```

Available numbers:  $0, 1, \ldots, 255$ 

#### Addition

```
uint8_t a = 42;
uint8_t b = 89;
uint8_t r = a + b;
```

#### Subtraction

```
uint8_t a = 157;
uint8_t b = 23;
uint8_t r = a - b;
```

Available numbers:  $0, 1, \ldots, 255$ 

#### Addition

```
uint8_t a = 42;
uint8_t b = 89;
uint8_t r = a + b;
```

#### Subtraction

```
uint8_t a = 157;
uint8_t b = 23;
uint8_t r = a - b;
```

- ► All results are in the set of available numbers
- Larger set of available numbers: uint16\_t, uint32\_t, uint64\_t
- Basic principle is the same; for the moment stick with uint8\_t

#### Crossing the ten barrier

```
6+5 = ?

9+7 = ?

4+8 = ?
```

#### Crossing the ten barrier

```
6+5 = ?

9+7 = ?

4+8 = ?
```

- ▶ Inputs to addition are still from the set of available numbers
- Results are allowed to be larger than 9

#### Crossing the ten barrier

```
6+5 = ?

9+7 = ?

4+8 = ?
```

- ▶ Inputs to addition are still from the set of available numbers
- ▶ Results are allowed to be larger than 9
- Addition is allowed to produce a carry

#### Crossing the ten barrier

```
6+5 = ?

9+7 = ?

4+8 = ?
```

- ▶ Inputs to addition are still from the set of available numbers
- ▶ Results are allowed to be larger than 9
- Addition is allowed to produce a carry

#### What happens with the carry?

- ► Introduce the decimal positional system
- ▶ Write an integer A in two digits  $a_1a_0$  with

$$A = 10 \cdot a_1 + a_0$$

Note that at the moment  $a_1 \in \{0, 1\}$ 

### ...back to programming

```
uint8_t a = 184;
uint8_t b = 203;
uint8_t r = a + b;
```

#### ... back to programming

```
uint8_t a = 184;
uint8_t b = 203;
uint8_t r = a + b;
```

- ▶ The result r now has the value of 131
- ► The carry is lost, what do we do?

#### ... back to programming

```
uint8_t a = 184;
uint8_t b = 203;
uint8_t r = a + b;
```

- ► The result r now has the value of 131
- ► The carry is lost, what do we do?
- Could cast to uint16\_t, uint32\_t etc., but that solves the problem only for this uint8\_t example
- We really want to obtain the carry, and put it into another uint8\_t

#### The AVR ATmega

- ▶ 8-bit RISC architecture
- ▶ 32 registers R0...R31, some of those are "special":
  - ► (R26,R27) aliased as X
  - ► (R28,R29) aliased as Y
  - ► (R30,R31) aliased as Z
  - X, Y, Z are used for addressing
  - 2-byte output of a multiplication always in R0, R1
- ► Most arithmetic instructions cost 1 cycle
- ▶ Multiplication and memory access takes 2 cycles

#### 184 + 203

```
LDI R5, 184
LDI R6, 203
ADD R5, R6 ; result in R5, sets carry flag
CLR R6 ; set R6 to zero
ADC R6,R6 ; add with carry, R6 now holds the carry
```

#### Addition

```
42 + 78 = ?

789 + 543 = ?

7862 + 5275 = ?
```

#### Addition

$$42 + 78 = ?$$
  
 $789 + 543 = ?$   
 $7862 + 5275 = ?$ 

$$7862 + 5275 + 7$$

#### Addition

```
42 + 78 = ?

789 + 543 = ?

7862 + 5275 = ?
```

$$7862 + 5275 + 37$$

#### Addition

```
42 + 78 = ?

789 + 543 = ?

7862 + 5275 = ?
```

$$7862 + 5275 + 137$$

#### Addition

$$42 + 78 = ?$$
  
 $789 + 543 = ?$   
 $7862 + 5275 = ?$ 

$$7862 + 5275 + 13137$$

#### Addition

$$42 + 78 = ?$$
  
 $789 + 543 = ?$   
 $7862 + 5275 = ?$ 

$$7862 + 5275 + 13137$$

 Once school kids can add beyond 1000, they can add arbitrary numbers

#### Multiprecision addition is old

"Oh Līlāvatī, intelligent girl, if you understand addition and subtraction, tell me the sum of the amounts 2, 5, 32, 193, 18, 10, and 100, as well as [the remainder of] those when subtracted from 10000."

—"Līlāvatī" by Bhāskara (1150)

#### AVR multiprecision addition...

- $\blacktriangleright$  Add two *n*-byte numbers, returning an n+1 byte result:
- ► Input pointers X,Y, output pointer Z

LD R5,X+	LD R5,X+
LD R6,Y+	LD R6,Y+
ADD R5,R6	ADC R5,R6

▶ Problem: Need 3n + c registers for  $n \times n$ -byte multiplication

- ▶ Problem: Need 3n + c registers for  $n \times n$ -byte multiplication
- ightharpoonup Can add on the fly, get down to 2n+c, but more carry handling

#### Can we do better?

"Again as the information is understood, the multiplication of 2345 by 6789 is proposed; therefore the numbers are written down; the 5 is multiplied by the 9, there will be 45; the 5 is put, the 4 is kept; and the 5 is multiplied by the 8, and the 9 by the 4 and the products are added to the kept 4; there will be 80; the 0 is put and the 8 is kept; and the 5 is multiplied by the 7 and the 9 by the 3 and the 4 by the 8, and the products are added to the kept 8; there will be 102; the 2 is put and the 10 is kept in hand..."

From "Fibonacci's Liber Abaci" (1202) Chapter 2 (English translation by Sigler)

#### Even better...?

From the Treviso Arithmetic, 1478 (http://www.republicaveneta.com/doc/abaco.pdf)

### Hybrid multiplication

- ▶ Idea: Chop whole multiplication into smaller blocks
- ► Compute each of the smaller multiplications by schoolbook
- Later add up to the full result
- ► See it as two nested loops:
  - Inner loop performs operand scanning
  - Outer loop performs product scanning

### Hybrid multiplication

- ▶ Idea: Chop whole multiplication into smaller blocks
- ► Compute each of the smaller multiplications by schoolbook
- ► Later add up to the full result
- See it as two nested loops:
  - Inner loop performs operand scanning
  - Outer loop performs product scanning
- Originally proposed by Gura, Patel, Wander, Eberle, Chang Shantz, 2004

#### Hybrid multiplication

- ► Idea: Chop whole multiplication into smaller blocks
- ► Compute each of the smaller multiplications by schoolbook
- Later add up to the full result
- See it as two nested loops:
  - Inner loop performs operand scanning
  - Outer loop performs product scanning
- Originally proposed by Gura, Patel, Wander, Eberle, Chang Shantz, 2004
- ► Various improvements, consider 160-bit multiplication:
  - ► Originally: 3106 cycles
  - Uhsadel, Poschmann, Paar (2007): 2881 cycles
  - ► Scott, Szczechowiak (2007): 2651 cycles
  - ► Kargl, Pyka, Seuschek (2008): 2593 cycles

### Operand-caching multiplication

- ► Hutter, Wenger, 2011: More efficient way to decompose multiplication
- Inside separate chunks use product-scanning
- ▶ Main idea: re-use values in registers for longer

### Operand-caching multiplication

- ► Hutter, Wenger, 2011: More efficient way to decompose multiplication
- Inside separate chunks use product-scanning
- Main idea: re-use values in registers for longer
- Performance:
  - ▶ 2393 cycles for 160-bit multiplication
  - ▶ 6121 cycles for 256-bit multiplication

### Operand-caching multiplication

- ► Hutter, Wenger, 2011: More efficient way to decompose multiplication
- Inside separate chunks use product-scanning
- Main idea: re-use values in registers for longer
- Performance:
  - ▶ 2393 cycles for 160-bit multiplication
  - ▶ 6121 cycles for 256-bit multiplication
- Followup-paper by Seo and Kim: "Consecutive operand caching":
  - ▶ 2341 cycles for 160-bit multiplication
  - ▶ 6115 cycles for 256-bit multiplication

- $\blacktriangleright$  So far, multiplication of 2 n-byte numbers needs  $n^2$  MULs
- ► Kolmogorov conjectured 1952: You can't do better, multiplication has quadratic complexity

- $\blacktriangleright$  So far, multiplication of 2 n-byte numbers needs  $n^2$  MULs
- ► Kolmogorov conjectured 1952: You can't do better, multiplication has quadratic complexity
- ▶ Proven wrong by 23-year old student Karatsuba in 1960

lacktriangle Recursive application yields  $\Theta(n^{\log_2 3})$  runtime

# Does that help on the AVR?

Consider multiplication of n-byte numbers

$$A \stackrel{.}{=} (a_0,\ldots,a_{n-1})$$
 and  $B \stackrel{.}{=} (b_0,\ldots,b_{n-1})$ 

Consider multiplication of n-byte numbers

$$A \stackrel{.}{=} (a_0,\ldots,a_{n-1})$$
 and  $B \stackrel{.}{=} (b_0,\ldots,b_{n-1})$ 

▶ Write  $A=A_\ell+2^{8k}A_h$  and  $B=B_\ell+2^{8k}B_h$  for k-byte integers  $A_\ell,A_h,B_\ell$ , and  $B_h$  and k=n/2

#### Consider multiplication of n-byte numbers

$$A \stackrel{.}{=} (a_0,\ldots,a_{n-1})$$
 and  $B \stackrel{.}{=} (b_0,\ldots,b_{n-1})$ 

- Write  $A = A_{\ell} + 2^{8k}A_h$  and  $B = B_{\ell} + 2^{8k}B_h$  for k-byte integers  $A_{\ell}, A_h, B_{\ell}$ , and  $B_h$  and k = n/2
- ightharpoonup Compute  $L = A_{\ell} \cdot B_{\ell} = (\ell_0, \dots, \ell_{n-1})$
- ► Compute  $H = A_h \cdot B_h = (h_0, \dots, h_{n-1})$
- lacksquare Compute  $M=(A_\ell+A_h)\cdot (B_\ell+B_h)\,\hat{=}\,(m_0,\ldots,m_n)$

#### Consider multiplication of n-byte numbers

$$A \stackrel{.}{=} (a_0, \dots, a_{n-1})$$
 and  $B \stackrel{.}{=} (b_0, \dots, b_{n-1})$ 

- ▶ Write  $A = A_{\ell} + 2^{8k}A_h$  and  $B = B_{\ell} + 2^{8k}B_h$  for k-byte integers  $A_{\ell}, A_h, B_{\ell}$ , and  $B_h$  and k = n/2
- ightharpoonup Compute  $L = A_{\ell} \cdot B_{\ell} = (\ell_0, \dots, \ell_{n-1})$
- ► Compute  $H = A_h \cdot B_h = (h_0, \dots, h_{n-1})$
- ► Compute  $M = (A_{\ell} + A_h) \cdot (B_{\ell} + B_h) = (m_0, \dots, m_n)$
- ▶ Obtain result as  $A \cdot B = L + 2^{8k}(M L H) + 2^{8n}H$

# Multiplication by the carry in ${\cal M}$

- ► Can expand carry to 0xff or 0x00
- Use AND instruction for multiplication

## Multiplication by the carry in ${\cal M}$

- ► Can expand carry to 0xff or 0x00
- ► Use AND instruction for multiplication
- Does not help for recursive Karatsuba

## Multiplication by the carry in M

- ► Can expand carry to 0xff or 0x00
- Use AND instruction for multiplication
- Does not help for recursive Karatsuba

#### Subtractive Karatsuba

- ightharpoonup Compute  $L = A_{\ell} \cdot B_{\ell} = (\ell_0, \dots, \ell_{n-1})$
- ightharpoonup Compute  $H = A_h \cdot B_h = (h_0, \dots, h_{n-1})$
- ► Compute  $M = |A_{\ell} A_h| \cdot |B_{\ell} B_h| = (m_0, \dots, m_{n-1})$
- ▶ Set t = 0, if  $M = (A_{\ell} A_h) \cdot (B_{\ell} B_h)$ ; t = 1 otherwise
- Compute  $\hat{M} = (-1)^t M = (A_\ell A_h)(B_\ell B_h)$  $\hat{=} (\hat{m}_0, \dots, \hat{m}_{n-1})$
- ▶ Obtain result as  $A \cdot B = L + 2^{8k}(L + H \hat{M}) + 2^{8n}H$

### The easy solution

$$if(b) a = -a$$

### The easy solution

$$if(b) a = -a$$

- ▶ NEG instruction does not help for multiprecision
- ► Can subtract from zero, but subtraction would overwrite zero

### The easy solution

$$if(b) a = -a$$

- ▶ NEG instruction does not help for multiprecision
- ► Can subtract from zero, but subtraction would overwrite zero
- ► Even worse, the if would create a timing side-channel!

#### The easy solution

$$if(b) a = -a$$

- ▶ NEG instruction does not help for multiprecision
- ► Can subtract from zero, but subtraction would overwrite zero
- ▶ Even worse, the if would create a timing side-channel!

#### The constant-time solution

- ► Produce condition bit as byte 0xff or 0x00
- XOR all limbs with this condition byte

#### The easy solution

$$if(b) a = -a$$

- ▶ NEG instruction does not help for multiprecision
- ► Can subtract from zero, but subtraction would overwrite zero
- Even worse, the if would create a timing side-channel!

#### The constant-time solution

- ► Produce condition bit as byte 0xff or 0x00
- XOR all limbs with this condition byte
- ► Negate the condition byte and obtain 0x01 or 0x00
- Add this value to the lowest byte
- Ripple through the carry (ADC with zero)

#### The easy solution

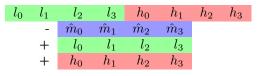

$$if(b) a = -a$$

- ▶ NEG instruction does not help for multiprecision
- ► Can subtract from zero, but subtraction would overwrite zero
- Even worse, the if would create a timing side-channel!

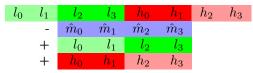

#### The constant-time solution

- ► Produce condition bit as byte 0xff or 0x00
- ► XOR all limbs with this condition byte
- ▶ Don't negate the condition byte
- Subtract the condition byte (0xff or 0x00 from all bytes)
- ► Saves two NEG instructions and the zero register

 $\blacktriangleright$  Consider example of  $4 \times 4$ -byte Karatsuba multiplication:

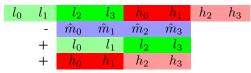

ightharpoonup Consider example of  $4 \times 4$ -byte Karatsuba multiplication:

- Karatsuba performs some additions twice
- ▶ Refined Karatsuba: do them only once

ightharpoonup Consider example of  $4 \times 4$ -byte Karatsuba multiplication:

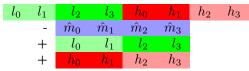

- Karatsuba performs some additions twice
- ► Refined Karatsuba: do them only once
- ▶ Merge additions into computation of *H*
- ► Compute  $\mathbf{H} = (\mathbf{h_0}, \mathbf{h_1}, \mathbf{h_2}, \mathbf{h_3}) = H + (l_2, l_3)$
- ► Note that **H** cannot "overflow"

 $\blacktriangleright$  Consider example of  $4 \times 4$ -byte Karatsuba multiplication:

- ► Karatsuba performs some additions twice

# Radix- $2^{64}$ representation

- ► Let's consider representing 255-bit integers
- ightharpoonup Obvious choice: use 4 64-bit integers  $a_0, a_1, a_2, a_3$  with

$$A = \sum_{i=0}^{3} a_i 2^{64i}$$

Arithmetic works just as before (except with larger registers)

# Radix- $2^{51}$ representation

- $\blacktriangleright\,$  Radix- $2^{64}$  representation works and is sometimes a good choice
- $\,\blacktriangleright\,$  Highly depends on the efficiency of handling carries

## Radix-2<sup>51</sup> representation

- ightharpoonup Radix- $2^{64}$  representation works and is sometimes a good choice
- ► Highly depends on the efficiency of handling carries
- Example 1: Intel Nehalem can do 3 additions every cycle, but only 1 addition with carry every two cycles (carries cost a factor of 6)

# $Radix-2^{51}$ representation

- ightharpoonup Radix- $2^{64}$  representation works and is sometimes a good choice
- ► Highly depends on the efficiency of handling carries
- ► Example 1: Intel Nehalem can do 3 additions every cycle, but only 1 addition with carry every two cycles (carries cost a factor of 6)
- Example 2: When using vector arithmetic, carries are typically lost (*very* expensive to recompute)

# Radix- $2^{51}$ representation

- ightharpoonup Radix- $2^{64}$  representation works and is sometimes a good choice
- ► Highly depends on the efficiency of handling carries
- ► Example 1: Intel Nehalem can do 3 additions every cycle, but only 1 addition with carry every two cycles (carries cost a factor of 6)
- Example 2: When using vector arithmetic, carries are typically lost (*very* expensive to recompute)
- $\blacktriangleright$  Let's get rid of the carries, represent A as  $(a_0, a_1, a_2, a_3, a_4)$  with

$$A = \sum_{i=0}^{4} a_i 2^{51 \cdot i}$$

lacktriangle This is called radix- $2^{51}$  representation

# Radix- $2^{51}$ representation

- ightharpoonup Radix- $2^{64}$  representation works and is sometimes a good choice
- ► Highly depends on the efficiency of handling carries
- ► Example 1: Intel Nehalem can do 3 additions every cycle, but only 1 addition with carry every two cycles (carries cost a factor of 6)
- ► Example 2: When using vector arithmetic, carries are typically lost (*very* expensive to recompute)
- ▶ Let's get rid of the carries, represent A as  $(a_0, a_1, a_2, a_3, a_4)$  with

$$A = \sum_{i=0}^{4} a_i 2^{51 \cdot i}$$

- ▶ This is called radix-2<sup>51</sup> representation
- ▶ Multiple ways to write the same integer A, for example  $A = 2^{52}$ :
  - $\triangleright$   $(2^{52}, 0, 0, 0, 0)$
  - $\triangleright$  (0, 2, 0, 0, 0)

## Radix-2<sup>51</sup> representation

- ightharpoonup Radix- $2^{64}$  representation works and is sometimes a good choice
- ► Highly depends on the efficiency of handling carries
- ► Example 1: Intel Nehalem can do 3 additions every cycle, but only 1 addition with carry every two cycles (carries cost a factor of 6)
- Example 2: When using vector arithmetic, carries are typically lost (*very* expensive to recompute)
- $\blacktriangleright$  Let's get rid of the carries, represent A as  $(a_0, a_1, a_2, a_3, a_4)$  with

$$A = \sum_{i=0}^{4} a_i 2^{51 \cdot i}$$

- ightharpoonup This is called radix- $2^{51}$  representation
- ▶ Multiple ways to write the same integer A, for example  $A = 2^{52}$ :
  - $\triangleright$   $(2^{52}, 0, 0, 0, 0)$
  - $\triangleright$  (0, 2, 0, 0, 0)
- Let's call a representation  $(a_0, a_1, a_2, a_3, a_4)$  reduced, if all  $a_i \in [0, \dots, 2^{52} 1]$

```
typedef struct{
  unsigned long long a[5];
} bigint255;
void bigint255_add(bigint255 *r,
                   const bigint255 *x,
                   const bigint255 *y)
 r->a[0] = x->a[0] + y->a[0];
  r->a[1] = x->a[1] + v->a[1];
  r-a[2] = x-a[2] + y-a[2];
  r->a[3] = x->a[3] + y->a[3];
 r->a[4] = x->a[4] + y->a[4];
```

```
typedef struct{
  unsigned long long a[5];
} bigint255;
void bigint255_add(bigint255 *r,
                   const bigint255 *x,
                   const bigint255 *v)
  r->a[0] = x->a[0] + y->a[0];
  r->a[1] = x->a[1] + v->a[1];
  r - a[2] = x - a[2] + y - a[2];
  r->a[3] = x->a[3] + v->a[3];
  r->a[4] = x->a[4] + y->a[4];
}
```

► This definitely works for reduced inputs

```
typedef struct{
  unsigned long long a[5];
} bigint255;
void bigint255_add(bigint255 *r,
                   const bigint255 *x,
                   const bigint255 *v)
  r->a[0] = x->a[0] + v->a[0];
  r->a[1] = x->a[1] + v->a[1];
  r - a[2] = x - a[2] + y - a[2];
  r->a[3] = x->a[3] + v->a[3];
  r->a[4] = x->a[4] + y->a[4];
}
```

- ► This definitely works for reduced inputs
- lacktriangle This actually works as long as all coefficients are in  $[0,\ldots,2^{63}-1]$

```
typedef struct{
  unsigned long long a[5];
} bigint255;
void bigint255_add(bigint255 *r,
                   const bigint255 *x,
                   const bigint255 *v)
  r->a[0] = x->a[0] + v->a[0];
  r->a[1] = x->a[1] + v->a[1];
  r - a[2] = x - a[2] + y - a[2];
  r->a[3] = x->a[3] + v->a[3];
  r->a[4] = x->a[4] + y->a[4];
}
```

- ► This definitely works for reduced inputs
- lacktriangle This actually works as long as all coefficients are in  $[0,\ldots,2^{63}-1]$
- ▶ We can do quite a few additions before we have to carry (reduce)

## Subtraction of two bigint255

```
typedef struct{
  signed long long a[5];
} bigint255;
void bigint255_sub(bigint255 *r,
                   const bigint255 *x,
                   const bigint255 *y)
  r->a[0] = x->a[0] - y->a[0];
  r->a[1] = x->a[1] - v->a[1];
  r-a[2] = x-a[2] - y-a[2];
  r->a[3] = x->a[3] - y->a[3];
 r->a[4] = x->a[4] - y->a[4];
}
```

► Slightly update our bigint255 definition to work with *signed* 64-bit integers

### Subtraction of two bigint255

```
typedef struct{
  signed long long a[5];
} bigint255;
void bigint255_sub(bigint255 *r,
                   const bigint255 *x,
                   const bigint255 *y)
  r->a[0] = x->a[0] - v->a[0];
  r->a[1] = x->a[1] - v->a[1];
  r-a[2] = x-a[2] - y-a[2];
  r->a[3] = x->a[3] - v->a[3];
 r->a[4] = x->a[4] - y->a[4];
}
```

- ▶ Slightly update our bigint255 definition to work with *signed* 64-bit integers
- ▶ Reduced if coefficients are in  $[-2^{52} + 1, 2^{52} 1]$

# Carrying in radix- $2^{51}$

- ▶ With many additions, coefficients may grow larger than 63 bits
- ► They grow even faster with multiplication

# Carrying in radix- $2^{51}$

- ▶ With many additions, coefficients may grow larger than 63 bits
- ► They grow even faster with multiplication
- Eventually we have to *carry* en bloc:

```
signed long long carry = r.a[0] >> 51;
r.a[1] += carry;
carry <<= 51;
r.a[0] -= carry;</pre>
```

▶ Note: Addition code would look *exactly* the same for 5-coefficient polynomial addition

- ▶ Note: Addition code would look *exactly* the same for 5-coefficient polynomial addition
- lacktriangle This is no coincidence: We actually perform arithmetic in  $\mathbb{Z}[x]$
- ▶ Inputs to addition are 5-coefficient polynomials

- ▶ Note: Addition code would look *exactly* the same for 5-coefficient polynomial addition
- lacktriangle This is no coincidence: We actually perform arithmetic in  $\mathbb{Z}[x]$
- ▶ Inputs to addition are 5-coefficient polynomials
- ▶ Nice thing about arithmetic in  $\mathbb{Z}[x]$ : no carries!

- ▶ Note: Addition code would look *exactly* the same for 5-coefficient polynomial addition
- lacktriangle This is no coincidence: We actually perform arithmetic in  $\mathbb{Z}[x]$
- ▶ Inputs to addition are 5-coefficient polynomials
- ▶ Nice thing about arithmetic in  $\mathbb{Z}[x]$ : no carries!
- ▶ To go from  $\mathbb{Z}[x]$  to  $\mathbb{Z}$ , evaluate at the radix (this is a ring homomorphism)
- Carrying means evaluating at the radix

- Note: Addition code would look exactly the same for 5-coefficient polynomial addition
- lacktriangle This is no coincidence: We actually perform arithmetic in  $\mathbb{Z}[x]$
- ▶ Inputs to addition are 5-coefficient polynomials
- ▶ Nice thing about arithmetic in  $\mathbb{Z}[x]$ : no carries!
- ▶ To go from  $\mathbb{Z}[x]$  to  $\mathbb{Z}$ , evaluate at the radix (this is a ring homomorphism)
- ► Carrying means evaluating at the radix
- Thinking of multiprecision integers as polynomials is very powerful for efficient arithmetic

- ► On some microarchitectures floating-point arithmetic is much faster than integer arithmetic
- ► An IEEE-754 floating-point number has value

$$(-1)^s \cdot (1.b_{m-1}b_{m-2}\dots b_0) \cdot 2^{e-t}$$
 with  $b_i \in \{0,1\}$

  - t = 127
- ightharpoonup Exponent = 0 used to represent 0
- ▶ Any number that can be represented like this, will be precise
- Other numbers will be rounded, according to a rounding mode

#### Addition and subtraction

```
typedef struct{
  double a[12];
} bigint255;
void bigint255_add(bigint255 *r,
                   const bigint255 *x,
                   const bigint255 *y)
  int i;
  for(i=0;i<12;i++)
    r-a[i] = x-a[i] + y-a[i];
}
void bigint255_sub(bigint255 *r,
                   const bigint255 *x,
                   const bigint255 *y)
  int i;
  for(i=0;i<12;i++)
    r-a[i] = x-a[i] - y-a[i];
}
```

► For carrying integers we used a right shift (discard lowest bits)

- For carrying integers we used a right shift (discard lowest bits)
- ► For floating-point numbers we can use multiplication by the inverse of the radix
- ▶ Example: Radix  $2^{22}$ , multiply by  $2^{-22}$
- ▶ This does *not* cut off lowest bits, need to round

- For carrying integers we used a right shift (discard lowest bits)
- ► For floating-point numbers we can use multiplication by the inverse of the radix
- ightharpoonup Example: Radix  $2^{22}$ , multiply by  $2^{-22}$
- ► This does *not* cut off lowest bits, need to round
- ▶ Some processors have efficient rounding instructions, e.g., vroundpd

- For carrying integers we used a right shift (discard lowest bits)
- ► For floating-point numbers we can use multiplication by the inverse of the radix
- ▶ Example: Radix  $2^{22}$ , multiply by  $2^{-22}$
- ► This does *not* cut off lowest bits, need to round
- ▶ Some processors have efficient rounding instructions, e.g., vroundpd
- ► Otherwise (for double-precision):
  - add constant  $2^{52} + 2^{51}$
  - ightharpoonup subtract constant  $2^{52} + 2^{51}$
  - ► This will round the number to an integer according to the rounding mode (to nearest, towards zero, away from zero, or truncate)

- ► We don't just need arithmetic on big integers
- ▶ We need arithmetic in finite fields

- ► We don't just need arithmetic on big integers
- ▶ We need arithmetic in finite fields
- lacktriangle In other words, we need reduction modulo a prime p

- We don't just need arithmetic on big integers
- ▶ We need arithmetic in finite fields
- ightharpoonup In other words, we need reduction modulo a prime p
- Let's fix some size and representation:

```
/* 256-bit integers in radix 2^16 */
typedef signed long long bigint[16];
```

- ▶ Integer A is obtained as  $\sum_{i=0}^{15} a_i 2^{16i}$
- ▶ Lot of space in top of limbs to accumulate carries

#### A quick look at product-scanning multiplication

```
/* 256-bit integers in radix 2^16 */
typedef signed long long bigint[16];
void mul_prodscan(signed long long r[31],
                  const bigint x,
                  const bigint y)
  r[0] = x[0] * y[0];
  r[1] = x[1] * y[0];
  r[1] += x[0] * y[1];
 r[2] = x[2] * y[0];
  r[2] += x[1] * y[1];
  r[2] += x[0] * y[2];
  r[29] = x[15] * y[14];
  r[29] += x[14] * y[15];
  r[30] = x[15] * y[15];
}
```

ightharpoonup Let's fix some p, say  $p=2^{255}-19$ 

- Let's fix some p, say  $p = 2^{255} 19$
- ▶ We know that  $2^{255} \equiv 19 \pmod{p}$
- ▶ This means that  $2^{256} \equiv 38 \pmod{p}$

- Let's fix some p, say  $p = 2^{255} 19$
- ightharpoonup We know that  $2^{255} \equiv 19 \pmod{p}$
- ▶ This means that  $2^{256} \equiv 38 \pmod{p}$
- ▶ Reduce 31-bit intermediate result r as follows:

```
for(i=0;i<15;i++)
r[i] += 38*r[i+16];
```

- Let's fix some p, say  $p = 2^{255} 19$
- ightharpoonup We know that  $2^{255} \equiv 19 \pmod{p}$
- ▶ This means that  $2^{256} \equiv 38 \pmod{p}$
- ▶ Reduce 31-bit intermediate result r as follows:

```
for(i=0;i<15;i++)
r[i] += 38*r[i+16];
```

- Let's fix some p, say  $p = 2^{255} 19$
- ▶ We know that  $2^{255} \equiv 19 \pmod{p}$
- ▶ This means that  $2^{256} \equiv 38 \pmod{p}$
- ▶ Reduce 31-bit intermediate result r as follows:

```
for(i=0;i<15;i++)
r[i] += 38*r[i+16];
```

► Result is in r[0],...,r[15]

#### Primes are not rabbits

▶ "You cannot just simply pull some nice prime out of your hat!"

- ▶ "You cannot just simply pull some nice prime out of your hat!"
- ▶ In fact, very often we can.
- For cryptography we construct curves over fields of "nice" order

- "You cannot just simply pull some nice prime out of your hat!"
- ▶ In fact, very often we can.
- For cryptography we construct curves over fields of "nice" order
- Examples:
  - $\triangleright$  2<sup>192</sup> 2<sup>64</sup> 1 ("NIST-P192", FIPS186-2, 2000)
  - $ightharpoonup 2^{224} 2^{96} + 1$  ("NIST-P224", FIPS186-2, 2000)
  - $2^{256} 2^{224} + 2^{192} + 2^{96} 1$  ("NIST-P256", FIPS186-2, 2000)
  - $\triangleright$  2<sup>255</sup> 19 (Bernstein, 2006)
  - $ightharpoonup 2^{251} 9$  (Bernstein, Hamburg, Krasnova, Lange, 2013)
  - $ightharpoonup 2^{448} 2^{224} 1$  (Hamburg, 2015)

- "You cannot just simply pull some nice prime out of your hat!"
- ▶ In fact, very often we can.
- ► For cryptography we construct curves over fields of "nice" order
- Examples:
  - $\triangleright$  2<sup>192</sup> 2<sup>64</sup> 1 ("NIST-P192", FIPS186-2, 2000)
  - $ightharpoonup 2^{224} 2^{96} + 1$  ("NIST-P224", FIPS186-2, 2000)
  - $2^{256} 2^{224} + 2^{192} + 2^{96} 1$  ("NIST-P256", FIPS186-2, 2000)
  - $\triangleright$  2<sup>255</sup> 19 (Bernstein, 2006)
  - $ightharpoonup 2^{251} 9$  (Bernstein, Hamburg, Krasnova, Lange, 2013)
  - $\triangleright$  2<sup>448</sup> 2<sup>224</sup> 1 (Hamburg, 2015)
- ▶ All these primes come with (more or less) fast reduction algorithms

- "You cannot just simply pull some nice prime out of your hat!"
- ▶ In fact, very often we can.
- For cryptography we construct curves over fields of "nice" order
- Examples:
  - $\triangleright$  2<sup>192</sup> 2<sup>64</sup> 1 ("NIST-P192", FIPS186-2, 2000)
  - $ightharpoonup 2^{224} 2^{96} + 1$  ("NIST-P224", FIPS186-2, 2000)
  - $2^{256} 2^{224} + 2^{192} + 2^{96} 1$  ("NIST-P256", FIPS186-2, 2000)
  - $\triangleright$  2<sup>255</sup> 19 (Bernstein, 2006)
  - $ightharpoonup 2^{251} 9$  (Bernstein, Hamburg, Krasnova, Lange, 2013)
  - $\triangleright$  2<sup>448</sup> 2<sup>224</sup> 1 (Hamburg, 2015)
- ▶ All these primes come with (more or less) fast reduction algorithms
- More about general primes later
- ▶ For the moment let's stick to  $2^{255} 19$

# Carrying after multiplication

```
long long c;
for(i=0;i<15;i++)
  c = r[i] >> 16;
  r[i+1] += c;
  c <<= 16;
  r[i] -= c;
c = r[15] >> 16;
r[0] += 38*c;
c <<= 16;
r[15] -= c;
```

# Carrying after multiplication

```
long long c;
for(i=0;i<15;i++)
  c = r[i] >> 16;
  r[i+1] += c;
  c <<= 16;
  r[i] -= c;
c = r[15] >> 16;
r[0] += 38*c;
c <<= 16;
r[15] -= c;
```

► Coefficient r[0] may still be too large: carry again to r[1]

## How about squaring?

#define bigint\_square(R,X) bigint\_mul(R,X,X)

# How about squaring?

```
/* 256-bit integers in radix 2^16 */
typedef signed long long bigint[16];
void square_prodscan(signed long long r[31],
                    const bigint x)
  r[0] = x[0] * x[0]:
 r[1] = x[1] * x[0];
 r[1] += x[0] * x[1];
  r[2] = x[2] * x[0];
  r[2] += x[1] * x[1]:
  r[2] += x[0] * x[2];
  r[29] = x[15] * x[14];
  r[29] += x[14] * x[15];
  r[30] = x[15] * x[15];
```

# How about squaring?

```

=0xA9FB57DBA1EEA9BC3E660A909D838D726E3BF623D

Another example: Pairing-friendly curves are typically defined over fields  $\mathbb{F}_p$  where p has *some* structure, but hard to exploit for fast arithmetic

- ▶ We have the following problem:
  - ightharpoonup We multiply two n-limb big integers and obtain a 2n-limb result t
  - ightharpoonup We need to find  $t \mod p$

- ▶ We have the following problem:
  - $\blacktriangleright$  We multiply two n-limb big integers and obtain a 2n-limb result t
  - ightharpoonup We need to find  $t \mod p$
- ▶ Idea: Perform big-integer division with remainder (expensive!)

- ▶ We have the following problem:
  - $\blacktriangleright$  We multiply two n-limb big integers and obtain a 2n-limb result t
  - ightharpoonup We need to find  $t \mod p$
- ▶ Idea: Perform big-integer division with remainder (expensive!)
- ▶ Better idea (Montgomery, 1985):
  - ▶ Let R be such that gcd(R, p) = 1 and t
  - ▶ Represent an element a of  $\mathbb{F}_p$  as  $aR \mod p$
  - Multiplication of aR and bR yields  $t = abR^2$  (2n limbs)
  - Now compute Montgomery reduction:  $tR^{-1} \mod p$

- ▶ We have the following problem:
  - lacktriangle We multiply two n-limb big integers and obtain a 2n-limb result t
  - ightharpoonup We need to find  $t \mod p$
- ▶ Idea: Perform big-integer division with remainder (expensive!)
- ▶ Better idea (Montgomery, 1985):
  - ▶ Let R be such that gcd(R, p) = 1 and t
  - ▶ Represent an element a of  $\mathbb{F}_p$  as  $aR \mod p$
  - Multiplication of aR and bR yields  $t = abR^2$  (2n limbs)
  - Now compute *Montgomery reduction*:  $tR^{-1} \mod p$
  - For some choices of R this is more efficient than division
  - ▶ Typical choice for radix-b representation:  $R = b^n$

# Montgomery reduction (pseudocode)

```
Require: p = (p_{n-1}, ..., p_0)_b with gcd(p, b) = 1, R = b^n,
  p' = -p^{-1} \mod b and t = (t_{2n-1}, \dots, t_0)_b
Ensure: tR^{-1} \mod p
  A \leftarrow t
  for i from 0 to n-1 do
       u \leftarrow a_i p' \mod b
       A \leftarrow A + u \cdot p \cdot b^i
  end for
  A \leftarrow A/b^n
  if A > p then
       A \leftarrow A - p
  end if
  return A
```

- ► Some cost for transforming to Montgomery representation and back
- Only efficient if many operations are performed in Montgomery representation

- ► Some cost for transforming to Montgomery representation and back
- Only efficient if many operations are performed in Montgomery representation
- ▶ The algorithms takes  $n^2 + n$  multiplication instructions
- ightharpoonup n of those are "shortened" multiplications (modulo b)

- ► Some cost for transforming to Montgomery representation and back
- Only efficient if many operations are performed in Montgomery representation
- ▶ The algorithms takes  $n^2 + n$  multiplication instructions
- ightharpoonup n of those are "shortened" multiplications (modulo b)
- ► The cost is roughly the same as schoolbook multiplication

- Some cost for transforming to Montgomery representation and back
- Only efficient if many operations are performed in Montgomery representation
- ▶ The algorithms takes  $n^2 + n$  multiplication instructions
- ightharpoonup n of those are "shortened" multiplications (modulo b)
- ▶ The cost is roughly the same as schoolbook multiplication
- Careful about conditional subtraction (timing attacks!)

- Some cost for transforming to Montgomery representation and back
- Only efficient if many operations are performed in Montgomery representation
- ▶ The algorithms takes  $n^2 + n$  multiplication instructions
- ightharpoonup n of those are "shortened" multiplications (modulo b)
- ▶ The cost is roughly the same as schoolbook multiplication
- ► Careful about conditional subtraction (timing attacks!)
- One can merge schoolbook multiplication with Montgomery reduction: "Montgomery multiplication"

# Still missing: inversion

▶ Inversion is typically *much* more expensive than multiplication

#### Still missing: inversion

- ▶ Inversion is typically *much* more expensive than multiplication
- ► Efficient ECC arithmetic avoids frequent inversions
- ► ECC can typically not avoid *all* inversions
- ▶ We need inversion, but we do (usually) not need it often

#### Still missing: inversion

- ▶ Inversion is typically *much* more expensive than multiplication
- ▶ Efficient ECC arithmetic avoids frequent inversions
- ► ECC can typically not avoid *all* inversions
- ▶ We need inversion, but we do (usually) not need it often
- ► Two approaches to inversion:
  - 1. Extended Euclidean algorithm
  - 2. Fermat's little theorem

## Extended Euclidean algorithm

- $\blacktriangleright$  Given two integers a, b, the Extended Euclidean algorithm finds
  - ightharpoonup The greatest common divisor of a and b
  - ▶ Integers u and v, such that  $a \cdot u + b \cdot v = \gcd(a, b)$

### Extended Euclidean algorithm

- $\blacktriangleright$  Given two integers a, b, the Extended Euclidean algorithm finds
  - ► The greatest common divisor of a and b
  - Integers u and v, such that  $a \cdot u + b \cdot v = \gcd(a, b)$
- ▶ It is based on the observation that

$$gcd(a, b) = gcd(b, a - qb) \quad \forall q \in \mathbb{Z}$$

## Extended Euclidean algorithm

- $\blacktriangleright$  Given two integers a, b, the Extended Euclidean algorithm finds
  - ► The greatest common divisor of a and b
  - Integers u and v, such that  $a \cdot u + b \cdot v = \gcd(a, b)$
- ▶ It is based on the observation that

$$gcd(a, b) = gcd(b, a - qb) \quad \forall q \in \mathbb{Z}$$

▶ To compute  $a^{-1} \pmod{p}$ , use the algorithm to compute

$$a \cdot u + p \cdot v = \gcd(a, p) = 1$$

Now it holds that  $u \equiv a^{-1} \pmod{p}$ 

# Extended Euclidean algorithm (pseudocode)

```
Require: Integers a and b.
Ensure: An integer tuple (u, v, d) satisfying a \cdot u + b \cdot v = d = \gcd(a, b)
   u \leftarrow 1
   v \leftarrow 0
   d \leftarrow a
   v_1 \leftarrow 0
   v_3 \leftarrow b
   while (v_3 \neq 0) do
         q \leftarrow \lfloor \frac{d}{v_2} \rfloor
         t_3 \leftarrow d \mod v_3
         t_1 \leftarrow u - qv_1
         u \leftarrow v_1
         d \leftarrow v_3
         v_1 \leftarrow t_1
         v_3 \leftarrow t_3
   end while
   v \leftarrow \frac{d-au}{b}
   return (u, v, d)
```
